

Assignment 1

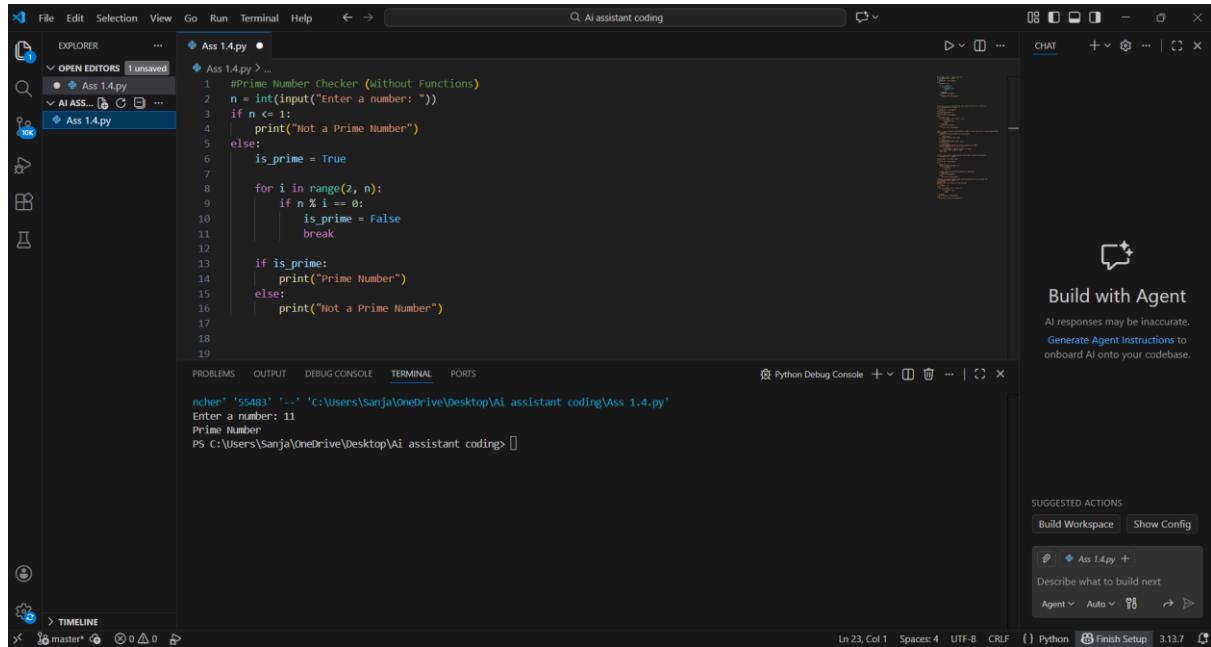

AI Assisted Coding

Name:-Bikkineni Sanjana

HTNO: 2303A52306

Task 1:

Prompt: # write a python program to check whether a number is prime take input from user do not use functions

The screenshot shows the Visual Studio Code interface with a dark theme. The left sidebar has an 'EXPLORER' view showing 'OPEN EDITORS' with 'Ass 1.4.py' and 'AI ASS...' listed. The main editor area contains the following Python code:

```
1 #Prime Number Checker (without Functions)
2 n = int(input("Enter a number: "))
3 if n <= 1:
4     print("Not a Prime Number")
5 else:
6     is_prime = True
7
8     for i in range(2, n):
9         if n % i == 0:
10             is_prime = False
11             break
12
13     if is_prime:
14         print("Prime Number")
15     else:
16         print("Not a Prime Number")
```

The terminal at the bottom shows the output of running the script with the input '11':

```
nchen` '55483' '--> 'C:\Users\Sanja\OneDrive\Desktop\AI assistant coding\Ass 1.4.py'
Enter a number: 11
Prime Number
PS C:\Users\Sanja\OneDrive\Desktop\AI assistant coding>
```

Observation:

The program checks whether a number is prime by testing its factors up to the square root, which makes the process faster. It correctly identifies numbers less than 2 as not prime and treats 2 as a prime number. The loop checks only odd numbers to reduce unnecessary calculations. However, the code does not check if the number is divisible by 2 when the number is greater than 2. Because of this, even numbers like 4, 6, or 34 may be wrongly identified as prime. Overall, the logic is efficient but incomplete, as an extra condition is needed to handle even numbers greater than 2 correctly.

Task 2:

Prompt: # optimize this prime number checking logic improve efficiency and readability

```

In 44, Col 4 Spaces: 4 UTF-8 CRLF { Python Finish Setup 3.13.7

Observation:

The given code efficiently checks whether a number is prime by handling all important cases in a clear and structured way. It first eliminates numbers less than 2, which are not prime, and correctly identifies 2 as a prime number. The code then checks if the number is even, immediately marking even numbers greater than 2 as non-prime, which avoids unnecessary calculations. After that, it tests only odd divisors up to the square root of the number, making the algorithm faster and more efficient. If any divisor is found, the function returns False; otherwise, it returns True. Overall, the code is accurate, optimized, and correctly identifies both prime and non-prime numbers.

Task 3:

Prompt:

Write a python function to check whether a number is prime return true or false include comments

In 87, Col 11 Spaces: 4 UTF-8 CRLF { Python Finish Setup 3.13.7

Observation:

The code correctly checks whether a number is prime by following a clear and efficient step-by-step approach. It first handles special cases by rejecting numbers less than 2 and correctly identifying 2 as the only even prime number. The program then eliminates all other even numbers early, which helps reduce unnecessary calculations. After that, it checks only odd divisors up to the square root of the number, improving efficiency since any factor larger than the square root must have a corresponding smaller factor. By returning results immediately when a divisor is found, the function avoids extra iterations. Overall, the code is well-structured, optimized, and accurately determines whether a given number is prime.

Task 4:

Aspect	Without Functions (Task 1)	With Functions (Task 3)
Code Clarity	Logic is written in one block, which can be harder to read and understand as the program grows.	Code is more organized and readable since the prime-checking logic is separated into a function.
Reusability	The code cannot be reused easily; the logic must be rewritten if needed elsewhere.	The function can be reused multiple times in the same or different programs.
Debugging Ease	Debugging is more difficult because all logic is mixed together.	Easier to debug since errors can be isolated within the function.
Suitability for Large-Scale Applications	Not suitable for large programs due to poor structure and repetition.	Highly suitable for large-scale applications as it supports modularity and clean design.

Task 5:

Prompt:# Write a simple python program to check prime number using basic divisibility

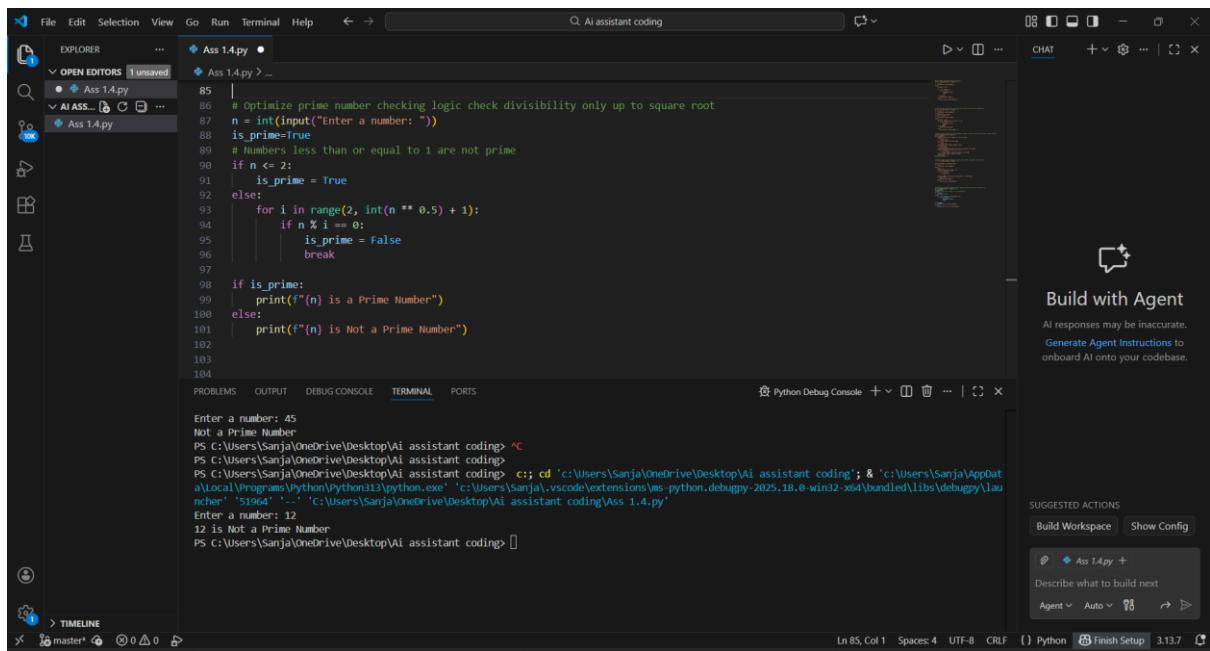

The screenshot shows the Visual Studio Code (VS Code) interface with an AI-assisted coding extension active. The top bar includes the standard File, Edit, Selection, View, Go, Run, Terminal, Help menus, and a back/forward navigation icon. A central search bar says "AI assistant coding". On the left, the Explorer sidebar shows an open folder named "Ass 1.4.py" containing files "Ass 1.4.py" and "Ass 1.4.ipynb". The main workspace displays the Python code for a prime number checker, with the first few lines highlighted in blue. To the right of the code, there's a preview pane showing the execution results. Below the code editor is a toolbar with Problems, Output, Debug Console, Terminal, and Ports buttons. The terminal at the bottom shows command-line interactions with the Python interpreter, including imports, file paths, and the execution of the script. A "CHAT" tab is visible on the far right.

Observation:

- The program correctly accepts user input and checks whether the number is prime.
- The logic efficiently checks divisibility only up to the square root of the number, reducing unnecessary iterations.
- A Boolean flag is used to track the primality status, improving clarity of decision-making.
- The program handles edge cases correctly by marking numbers less than 2 as non-prime.
- Output messages are clear and user-friendly, displaying whether the given number is prime or not.
- Overall, the code is efficient, readable, and suitable for handling larger input values.

Prompt:

Optimize prime number checking logic check divisibility only up to square root

The screenshot shows the Visual Studio Code interface with the following details:

- File Explorer:** Shows two files: "Ass 1.4.py" and "Ass 1.4.py".
- Code Editor:** Displays Python code for prime number checking. The code uses a for loop from 2 to the square root of n to check for divisibility. It includes comments explaining the logic and handles edge cases for numbers less than 2.
- Terminal:** Shows the command line output of running the script with input 45, which correctly identifies it as not a prime number.
- Right Panel:** Features an "AI assistant coding" interface with a "Build with Agent" section, a "SUGGESTED ACTIONS" button, and a "Python Debug Console" tab.

```

85 |
86 # Optimize prime number checking logic check divisibility only up to square root
87 n = int(input("Enter a number: "))
88 is_prime=True
89 # numbers less than or equal to 1 are not prime
90 if n <= 2:
91     is_prime = True
92 else:
93     for i in range(2, int(n ** 0.5) + 1):
94         if n % i == 0:
95             is_prime = False
96             break
97
98 if is_prime:
99     print(f"{n} is a Prime Number")
100 else:
101     print(f"{n} is Not a Prime Number")
102
103
104

```

Observation:

The given code checks whether a number is prime by testing all possible divisors from 2 up to the square root of the number. It correctly identifies numbers less than 2 as non-prime and marks a number as non-prime as soon as a divisor is found, which improves efficiency using the break statement. This approach is simple and easy to understand, making it suitable for beginners. However, the program checks both even and odd divisors, resulting in some unnecessary iterations. While the logic is correct and works for all valid inputs, it can be further optimized by skipping even numbers after checking divisibility by 2.
